Spatial Planning for Promoting Sustainable Development in Pachchilaipalli Divisional Secretariat in the Killinochchi District of Sri Lanka- A Case Study for Post-Conflict Development

¹Damith Chandrasekera and ¹Swarna Piyasiri

¹Department of Zoology, Faculty of Applied Sciences, University of Sri Jayewardenepura, Sri Lanka

ABSTRACT

Reconstruction and development in post-disaster or post conflict situations pose multiple challenges. These scenarios necessitate high investment for rapid reconstruction, socio-economic development to minimize future conflicts or disasters, and opportunities to introduce; landuse planning, environmental, engineering and other best practices for increased sustainability and resilience. The post-conflict situation in the Killinochchi District presents a scenario with agencies having outdated data, missing critical information, an intensive development drive which exerts pressures on nature, culture and large number of scattered development plans.

The study involves three stages, namely, establishment of baseline data, analysis of digital data and development of a zoning map as a proposed landuse. This facilitates the decision making in development activities within the area with environmental conservation, and coordinates stakeholder agencies for sustainable development.

The entire Killinochchi District was divided in to 92 equal grids for micro level planning and 5 Km² area in Pachchilaipalli DS Division was selected to initiate the case study. The topographical survey maps developed in 1956, 1983 and 2010 were used for spatial analysis, and to compare the landuse changes occurred during the last 57 years in the area of study. Arc GIS 10.1 software was used to develop spatial maps of different sectors. The zoning map which was prepared as the proposed landuse plan illustrates the spatial distribution of areas for development with minimum environmental impacts as the key output of the study.

KEYWORDS: *Post disaster, sustainable development, spatial planning, post-conflict*

1. INTRODUCTION

The Killinochchi District was one of the few districts that seriously affected due to the conflict of past three decades where environment and development (similar to all other sectors) have suffered heavily. However, due to the change in security situation since May 2009 has created a safe environment whereby the Government of Sri Lanka had gained total administrative control over the conflict affected areas including the Killinochchi district. This has created a favourable climate of optimism for moving forward with plans for development of the district to produce a peace dividend to the community. Government has launched a major development thrust “Uthuru Wasanthaya (Northern Spring)” which evolves development of settlements, urban and rural infrastructure and livelihood development.

There are multiple factors which makes the situation particularly challenging. Mainly the political need of the Government to demonstrate peace dividends and implement development projects in a rapid manner in the absence of a master plan for the development of Killinochchi district. These development plans challenge the sustainable development and threatens the protection of environmental resources. The usual environmental safeguards may be ignored under such situations and unplanned development could take place. The environmental management system cannot cope up with number of projects coming up in the area. Since there are no data for past 30 years in the area due to the war situation in the district, decisions may have to be taken based on insufficient or outdated information.

Since renewal programs had started into focus on livelihood development of the economically and socially disturbed areas, it was very relevant to undertake post conflict development with environmental assessment

of the present situation which is a novel concept to Sri Lanka.

Objectives

1. The objectives of the present study are to analyse the landuse data from 1956 to 2010 to find out the changes taken place particularly during war situation.
2. Using those information it is expected to develop a zoning map as a propose landuse plan to use for future development activities as a piece of Master Plan.

Therefore the purpose of this study was to understand the probable environmental consequences arised due the prolong conflict scenario and to introduce spatial solution to facilitate post conflict sustainable development in the area of study. The assessment focused to avoid development in environmentally sensitive or disaster-prone areas and to manage and control unplanned development whilst proposing suitable landuse to initiate national development goals. This assessment will help to avoid adverse impacts arising from implementation of unplanned development activities. It helps to introduce sustainable landuse planning, mitigatory measures to ensure environmental conservation and implement monitoring framework to facilitate disaster management for economic development and district planning. It will also facilitate and strengthen the sustainable development and environmental conservation process by helping policy makers and planners to take early account of the environmentally sensitive and disaster prone areas.

1.1 Area of Study

The specific geographical area of this research is limited only to a 5Km² grid area in Pachchilaipalli Divisional Secretary in the Killinochchi district (Figure 1). The area is administratively covered by 5 GN divisions

Respective agencies were consulted under the development phase to map the proposed development plans. In this process, District Secretary and district planning unit were consulted to incorporate the development plans and to share information on the process and intermediate products of the study. These development plans were incorporated to the resource map.

(c) Assessment phase

The key stakeholder agencies who were involved in conservation and development activities at local and central level were consulted to identify potential development scenarios, conflicts and mitigatory measures to overcome them. The assessment phase led to the spatial analysis and development of proposed landuse map (zoning Map).

2.2 Spatial Analysis

The digital data required to analyse the demographical and geographical characteristics in the area of study were obtained from the Survey Department. The topographical survey maps scale 1: 63360 (one inch to one mile) developed in 1956 were digitized and series of topographical survey maps in the scale of 1:50000 published in 1983 and 2010 were used to compare and find the landuse changes occurred during the last 57 years in the area of study. Further topographical maps at the scale of 1:10000 published by the Survey Department in 2010 were used for spatial analysis and presentation. The maps include the characteristics of landuse, transport, hydro and buildings. Further latest google earth spatial maps were used for comparison and ground verifications. Arc GIS 10.1 package was

used in the data analysis. The entire district was divided into 92 grid cells at a dimension of 5 Km² for micro level planning (Figure 1).

3. RESULTS AND DISCUSSION

The survey maps developed in 1956 (1 inch) depicted below as figure 3, 1983 (figure 4) and 2010 (1:50000/ 1: 10000) shown as figure 5 and 8 were used to compare the potential landuse changes and landuse practices taken place over last 56 years in the area of study. Those three maps represent equal intervals of 27 years each from 1956 to 2010. Further the satellite image of 2013 shown as figure 6 was used to verify the landuse changes of the study area.

Figure 6. Satellite image of 5Km² grid selected in Pachchilaipalli DS Division
Source: Satellite image -2013

The comparison of three spatial maps (Figure 3, 4 and 5) clearly indicates that certain landuse types were increased and some types were relatively decreased. The landuse type changes are indicated in figure 7.

Figure 7. Change of Landuse types (1956 – 2010)

As illustrated in Fig 7, the total land extent of coconut cultivation was drastically dropped from 1001 to 284 Ha (by 717 hectare) within the period from 1983 to 2010.

The area of forest had reduced by 118 hectare within the period from 1956 to 1983, as the area of forest was utilised for plantation crops, but it has regained nearly the same extent by 2010.

The extent of paddy during the period from 1956 to 1983 has no major difference but since 1983 the situation has changed and presently the area of paddy had decreased by 77 hectare (165 hectare to 88 hectare) which is almost 50% drop of land area.

The area for Residential area (homestead) has indicated an increase of 258 hectare during the period from 1956 to 1983 but the same had decrease by 156 hectare within the period from 1983 to 2010. The changes recorded in other landuse types are only marginal and are insignificant.

The landuse within the period from 1956 to 1983 provides clear indication of extensive

utilisation of land for agricultural and other livelihood purposes. The result illustrates a significant drop of utilisation of land for agriculture from 1983 - 2010, specially coconut, paddy and palmyra which are major agricultural products of the area. The fact is further strengthened with the evidence of an increasing trend of scrub land and forest extends after 1983. Further latest spatial images as indicated in figure 6 confirm that the areas used for plantations and agriculture had transformed into scrubs and new forest areas. A considerable decline of homestead is highlight after 1983 and the utilisations of land for other purposes were also in a declined state.

As a whole, it is understood that the people of the area had migrated at large to other parts of the country due to the prolong war since 1983 and even the movements of the people living within the area of study would have been restricted due to unsafe mobility and security reasons. Even though the livelihood and living condition of the people living in were considerably affected, the level of environmental degradation was found to be at minimal level as most of the environmental conservation indicators remain at a satisfactory standard.

The present landuse at the scale of 1:10000 (figure 8) was used for spatial analysis and presentation. Considering the landuse records since 1956 and scientific data, an appropriate landuse was proposed as mentioned in table 1 and same is presented in figure 9 & 10.

Zoning Map

The area of study was divided into six zones (figure 11) as follows, in order to plan for optimal utilization of existing land to maximise the productivity of land in line with National and regional development programmes – Vision for the Future first and second 5 year development framework,

Unstoppable Sri Lanka - 2020 and (2020), National Physical Plan - 2030, Uthuru Wasanthaya Programme etc.

- Commercial Zone
- Agricultural Zone
- Industrial Zone
- Tourism & Recreational Zone
- Protection/conservation Zone and,
- Residential Zone

Figure 9. Proposed landuse of 5Km² grid selected in Pachchilaipalli DS Division. Source: Survey Maps

Figure 10. Existing vs proposed landuse of 5Km² grid selected in Pachchilaipalli DS Division

Total 14 sectors were analysed within the period of 57 years from 1956. Zoning was done considering the landuse in 1956, 1983 and 2010.

The zoning was focused to facilitate the development with minimum environmental impacts. Further study considered to improve the socio economic status and livelihood opportunities of the community living in the area of study.

(a) Agricultural Zone

The plantation crops such as coconut, palmyra and palm are the three main plantation crops representing the landuse in the area of study. These plantation crops cover about 36% of the total land area. Out of plantation crops coconut was found to be covering the major land extent of 71% and palm has the minimum coverage of 5.41 ha. Since the district is located in low country dry zone with red-yellow latosols and regosols soil and the species represent the same family, these plantation crops are more suitable for plantation in the area of study.

Further the historical landuse records since 1956 also proves the fact as large extent of the area was utilized for plantation of these crops.

Table 1. Proposed landuse change of 5 km² grid area selected in Pachchilaipalli DS

Category	Existing Landuse extent (ha)	Propose land extent (ha)	Landuse change (ha)
Build up/ Commercial area	0.65	79.94	79.29
Barren land	29.89	0.00	-29.88
Service Road gravel	0.00	29.88	29.88
Plantation Crops(Coconut, Palmyra, Palm)	882.68	1,089.01	206.33
Forest	97.95	390.57	292.62
Grass land	24.35	0.00	-24.35
Settlement	157.84	247.04	89.20
Water bodies	175.11	175.11	0.00
Marsh	5.97	1.81	-4.16
Other crops	48.55	117.46	68.90
Paddy	180.11	270.37	90.26
Sand	24.33	0.00	-24.33
Tourism	0.00	10.47	10.47
Scrub	789.64	5.41	-784.22
Total	2,417.06	2,417.06	0.00

Figure 11. Zone Map - Proposed landuse zoning for 5 km² grid area selected in Pachchilaipalli DS Division . Source: 1:10000 Survey Map, 2010

Since coconut is a perennial crop which use only 25% of the soil, there is a great potential for growing other crops as intercrops and to promote animal husbandry under these plantation areas.

Table 2. Forecast for plantation crop expansion in the area of study

Type of Crop	Present extent- 2010 (ha)	Forecast (ha)	%
Coconut	626.8927	773.43	71.02
Palmyra	207.9907	256.61	23.56
Palm	47.7916	58.96	5.41
Total	882.675	1089.01	100.00

Source: 1:10000 Survey Map, 2010

The land extents of paddy and other crops sectors were also proposed to increase in order to expand the agricultural areas and to improve the productivity of land use. Seasonal and field crops such as chilies (green), black gram, red onions, groundnuts and potatoes etc. are proposed in line with 2020 development plan.

(b) Conservation Zone

Study propose 292 hectare increase of forest land since the identified new area for conservation is physically covered with dense forest and found to be marginally changed during last five decades. This fact is further strengthened by the satellite images and one inch landuse in 1956. Due to the increase in population and utilisation of forest for plantation agriculture, an extent of 63% forest area was reduced within the period from 1956 to 1983, but subsequently the area had increase considerably.

The study area consists 90 minor tanks/waterholes which count for about 175 hectare. Each water body was proposed with a 25meter buffer zone in order to protect the minor tanks/waterholes from encroachments.

The total area for the buffer zones is 98.75 hectare.

(c) Residential Zone

Considering the increasing trend of population and their livelihood activities, the total land extent for homestead is proposed to increase by 89 hectare. This is mainly for housing, promote home gardens and open space cultivation including fruit trees such as grapes and wood apple and small holdings of coconut and palmyra.

Further animal husbandry and broiler farms could be promoted to increase the backyard economy of households.

(d) Commercial/Build up Zone

The commercial /build up area is proposed to be increased from 0.65 hectare to 79.29 hectare. Under this study, this sector was given the highest percentage of land allocation than other sectors in order to facilitate the development whilst ensuring environmental conservation. The area proposed for future residential (including guest houses), commercial, institutional, administrative, transportation, small and medium scale industries and urban open spaces etc. Central, regional or other sublevel development plans in the area of interest were not reported.

(e) Industrial Zone

Since the government has planned to upgrade and modernize the Achchuvali Industrial Estate in Jaffna, major scale industries were not proposed. Further the area is not suitable for major industries as the area is more of agricultural based, environmentally sensitive and short of required infrastructural facilities. Since the area of study consist 90 minor tanks/waterholes which covered around 175

hectare, it is proposed to promote inland fishery as an activity of livelihood.

(f) Tourism and Recreational zone

According to the ISEA 2010 study, the area is enriched with forest, lagoon and wildlife including sea and wilding birds. An area of 10.47 hectare adjoining the lagoon and forest was proposed to promote ecotourism targeting local and foreign tourist. Most of the sand areas have been proposed to be utilized for the purpose.

The land identified as barren was found to be an uncropped road track. The total area proposed as a gravel road to be used as a service road for the maintenance of inland water bodies and access road to agricultural areas. The remaining areas under marsh and scrubs are found to be located in the lagoon which could not be utilised for any productive purpose. Extents of following unproductive/underutilized lands were proposed to be reduced as indicated in Table 3.

Table 3. Existing landuse proposed to reduce

Category	Existing Land area (ha)	Total propose land extent (ha)
Barren land	29.89	0.00
Grass land	24.35	0.00
Marsh	5.97	1.81
Scrub	789.64	5.41

Source: 1:10000 Survey Map, 2010

As per the ISEA 2010 and the Hazard Profile of Sri Lanka, the area of study found to be free from hazards such as floods and coastal hazards which are common to most of the other parts of the Killinichchi district. According to ISEA 2010 the area of study is vulnerable to drought and high winds as the

total land area of Killinochchi distract is within the very high drought vulnerable zone and classified under “zone one” in the wind loading study conducted after the East coast cyclone in 1979.

4. CONCLUSIONS & FUTURE RESEARCH

Due to the 30 years prolong war, the area of study was adversely affected in all aspects especially the physical and socio-economic development of the people who were living in the area of study were totally hampered. Therefore it is necessary to initiate development activities that were lag behind many years in a rapid and sustainable manner. At present development in Killinochchi district is taking place in rapid manner and it is essential to introduce a sustainable mechanism to achieve long-lasting development covering all segments of the society.

The study examined the spatial evolution of landuse changes at the contexts of pre, during and post conflict periods of the last 30 years within a pilot study area of 5km² grid area in Pachchilaipalli Divisional Secretary in the Killinochchi district (Figure 1).

As per the methodology, the study compared the changes in landuse in three different intervals from 1956 to 2010. Results showed a significant decline trend of population and related livelihood activities in the area of study due to the eruption of hostilities in 1983 and continued until cessation of conflict in 2009. Further, analysis indicates expansion of forest areas within the period of conflict. The study highlighted the effects of war on productive land, where most of the lands which were productive during the period from 1956 to 1983 were transformed in to infertile land by 2010.

The results provided a better understanding of the impact of 30 years of conflict in the study area. Although it was known in an anecdotal sense that impact of war had adversely affects on many sectors, the present analysis is unique in defining those effects in spatial terms, in showing its extent of change in landuse.

The future analysis on the area of study could grant an opportunity to validate the proposed landuse changes and the results of this study. This study can be particularly useful for district planning as a guide during strategic decision making and to identify suitable lands for future development activities.

The study intends to replicate in other 91equal slots covering the whole Killinochchi district and finally to prepare the district land use zoning map to facilitate future sustainable development in the Kilinochchi district.
